

Summary: Lecture 8

Summary for the chapters 9.3 and 9.4. [2, 1]

Undirected graph

An undirected graph G is a pair of sets (V, E) where V is the finite set of nodes and E is a set of unordered pairs in V that are symmetric:

$$\forall i, j \in V, i \neq j : (i, j) \in E \Rightarrow (j, i) \in E$$

IndependentSet

IndependentSet

Input: An undirected Graph $G = (V, E)$ and a number k .

Question: Is there a set $I \subseteq V$ of $k = |I|$ nodes with no edges in between? (INDEPENDENTSET)

3SAT

Like the SAT problem, 3SAT is determining the satisfiability of a formula in CNF where each clause is limited to at most three literals.

INDEPENDENTSET is NP-complete.

Proof idea:

- triangle construction: any independent set can contain at most one node of the triangle

$$(x_1 \vee x_2 \vee x_3) \wedge (\neg x_1 \vee \neg x_2 \vee \neg x_3) \wedge (\neg x_1 \vee x_2 \vee x_3)$$

Figure 1: Graph with triangles [2]

- consider only graphs whose nodes can be partitioned in m disjoint triangles
→ independent set can contain at most m nodes (one from each triangle)
- reduction from 3SAT to INDEPENDENTSET
- construct graph of formula ϕ :
 - each literal as a node
 - clauses as triangles
 - edges between nodes in different triangles if they correspond to the same literal (negated)
 - $K = m$ (m clauses)

- given: instance ϕ of 3SAT with m clauses C_1, \dots, C_m
- each clause $C_i = (\alpha_{i1} \vee \alpha_{i2} \vee \alpha_{i3})$ (with α as boolean variables or negation of those)
- reduction R constructs a graph: $R(\phi) = (G, K)$ where $K = m$ and $G = (V, E)$
- nodes $V = \{v_{ij} : i = 1, \dots, m; j = 1, 2, 3\}$
nodes for each of the m clauses (i) for each of the 3 literals (j)
- edges $E = \{[v_{ij}, v_{ik}] : i = 1, \dots, m; j \neq k\} \cup \{[v_{ij}, v_{lk}] : i \neq l, \alpha_i j = \neg \alpha_l k\}$
edges between the nodes in one clause (triangle edges)
edges between nodes with the same corresponding literal, but negated
- there is an independent set I of K nodes in G only if ϕ is satisfiable
- I must contain a node from each triangle
- negated literals are connected: I cannot contain a literal and its negation
- I is a truth assignment of ϕ :
 - true literals: nodes in I
 - one true literal per clause

HamiltonPath is NP-complete

HamiltonPath

A HAMILTONPATH is a path in a graph that visits each node exactly once.

HAMILTONPATH is NP-complete.

Proof idea:

- reduction from 3SAT to HAMILTONPATH
- given: formula ϕ in CNF with n variables x_1, \dots, x_n and m clauses C_1, \dots, C_m with each 3 variables
- construct a graph $R(\phi)$ that has a hamilton path only if ϕ is satisfiable:
- boolean variables:
 - choice between true and false
 - all occurrences of x must have the same value (and $\neg x$ the opposite)
 - use *choice* gadget (like flip flop)
- XOR:

Figure 2: XOR subgraph from the book [2] with the relevant edges marked additionally

- use *consistency* gadget
- because of hamilton path: there are only two ways to traverse through this sub graph (as shown above)
- leads to exclusive or (XOR)

Figure 3: XOR connecting two independent edges (*consistency* gadget) [2]

- clauses:
 - triangles for clause construction
 - one side for each literal
 - if literal is false: hamilton path traverses triangle side
 - at least one literal need to be true: else all three edges of triangle will be traversed and this is not a hamilton path
- put everything together as graph G :
 - G has n copies of the *choice* gadget as a chain (one for each variable)

Figure 4: *Choice* gadgets marked in graph from the book [2]

TODO

Questions:

TSP(D)

TSP(D)

TSP(D) is a decision version of TSP.

Input: A $n \times n$ distance matrix and a bound $B \in \mathbb{N}$

Question: Is there a round tour of length $\leq B$ that visits all *cities*?

TSP(D) is NP-complete.

Proof idea:

- budget of nodes is $B = |V| + 1$

TODO

Questions:

Knapsack

Knapsack

KNAPSACK is NP-complete.

- filled in in one dimensional array onthe board
-

TODO

Questions:
